

REPUBLIC OF RWANDA

MINISTRY OF AGRICULTURE AND ANIMAL RESOURCES

CROP ASSESSMENT - 2010B SEASON

PRELIMINARY REPORT

31 July 2010

1. Introduction

The Ministry of Agriculture and Animal Resources (MINAGRI), in collaboration with RADA, the National Institute of Statistics of Rwanda (NISR), FAO and WFP organizes, each agricultural season, a crop assessment survey. One of the objectives of this survey is to estimate the food balance and plan for food requirements within the next six months. Also, results from this exercise are used in the estimation of the gross domestic product (GDP) and the contribution of the sector in the national economy.

Data are collected by enumerators recruited by MINAGRI, under the supervision of staff from MINAGRI, RADA, NISR, FAO and WFP. Field activities are organized in two phases. The first phase began with the beginning of season 2010 B with the objective of measuring cultivated areas and expected production for each crop (done in march 2010). The second phase occurred during the third week of may and aimed at collecting the production of the season.

2. Sampling methodology.

The methodology used in the crop assessment exercise is the one used for the National Agriculture Survey (ENA 2008) organized by the National Institute of Statistics of Rwanda (NISR), in collaboration with the Ministry of Agriculture and Animal Resources. The sample size for the crop assessment survey represents 25% of the National Agriculture Survey. At the first stage, 210 primary sampling units (PSU) or enumeration areas (EA) have been selected using the simple random sampling method and then 15 households (12 for interview and 3 households for replacement) per EA have been selected. In fact, the same households selected for the ENA have been covered by the crop assessment exercise, which represent 2,520 sample households.

The sampling frame of the ENA is described in Gashaka Jacques « Sampling frame and estimation procedures », Novembre 2007. The summary of the sampling methodology is presented in annex 1.

3. Data collection methodology.

3.1. Area measurement

The shape of cultivated areas is not always of the regular form (triangle, rectangle...), but most of the fields under cultivation have rectangular shape (square or rectangle), others are triangular (triangle). We encounter also fields that have irregular shape, having 5 sides or above. In one or other case, the area measurement has been done by triangulation method (splitting the plot in triangles or rectangle). Hence, the area of the plot is the total sum of the surface areas of the triangles (or rectangle, square) created in that plot.

3.2. Density estimation and crop areas.

It's a common in Rwanda to have intercropping practice. In one parcel, it can be planted beans, sweet potato and sorghum. The question that arises is to estimate the area allocated to each of these crops, i.e, which area is allocated to a particular crop planted in this parcel in the absence of intercropping (one single crop in the parcel)?

Density of each crop in the parcel are roughly estimated de visu and standardized by dividing density for particular crop by the sum of the densities of all crops (the standardized densities sum up to 100). The area for each crop is equal to the standardized density multiply by the area of the parcel. These densities are used to estimate the percentage of land allocated to each crop by district. These estimates are applied to the total area under cultivation by district to obtain the total land for each crop.

3.3. Estimation of Production.

Under each particular piece of land, the enumerator asks the head of household what quantity of each crop present in that parcel, to be harvested during season 2010B. The expected production includes the quantity harvested before the interview and the quantity to be harvested until december 2010.

He production can be expressed in differeent units of measurement (Kg, bag, basket, bucket, ...). It is asked to the enumerator to convert theses units in Kg.

3.4. Data processing and analysis.

Data entry mask has been designed using CsPro (Census and Survey data Processing). Data editing included the checking of range, structure, and a selected set of checks for internal consistency. All errors detected during the editing procedure were corrected. Statistical tables have been prepared using SPSS. These tables were transferred to Excel spreadsheet for further calculations.

All crop and animal products were converted to their equivalent Kcal, proteins and lipids using the appropriate weights of each commodity. The population was estimated at mid seasonal time, August 31st, 2010. Assuming a daily adult requirement of 2100 kcal/capital/day, 59 g of proteins and 40 g of lipids (source ENA/MINAGRI), the total Kcal was shared among the Rwandan population for six months (181 days) calculated at August 31st, 2010.

Losses through cooking and post-harvest handling were estimated at 15% since most of the produce in Rwanda is consumed almost immediately.

Comparisons were made between production in 2009B and 2010B for the different crops and products. The food balance sheet was then computed using the following formula:

1. Available food for human consumption=1+2+3
2. Amount available in stock=7000 T
3. Production (x 1000 MT)=Energy (Kcal/Capital/day)/equivalent Kcal for maize (i.e. 3225.32 Kcal/Kg) x 1000
4. Losses= -0.2 x crop production
5. Needs= 4
6. Consumption=2100x181daysxestimated population/3225.32/1000000
7. Balance/Deficit=1-5

4. Key Results.

4.1. Area under crop.

The land area measured in the crop assessment exercise consists of the land under cultivation and of which the planted crops will be harvested within the next six months following the end of the season.

Graph 1-1 shows that in comparison with 2009B, harvested area increased by 8% for cereals, 11% for tubers, 5% for vegetables and fruits. In general, land area went up by 2%; while land area for pulses and banana diminished by 9% and 3% respectively.

As regard the share of land occupied by each crop, the distribution of the share of land in 2010B for each individual crop is as follows: 16% for beans, 1% for rice, 4% for wheat, 7% for maize, 14% for sorghum, 11% for cassava, 8% for sweet potato, 8% for Irish potato and 18% for banana.

4.2. Expected production in 2010C (Maize and vegetables in marshlands).

In its efforts to promote horticulture in Rwanda, the MINAGRI has distributed improved vegetable seeds to be planted in 2010, in marshlands. It's worth noting that the production of the season C occurs between July and the end of the year and therefore, it must be included in the food availability of the second half of the year (July - December).

During season 2010C, MINAGRI/Rhoda distributed 2,479 Kgs of improved (against 2,030 Kg distributed in 2009C) vegetable seeds to be planted on 2,601 Ha. Vegetable crops for which seeds have been distributed are Cabbage, Eggplant, Carrot, Tomato, Sweet pepper, Amaranthus, Red Onions, White onions, French beans, Lettuce, Cauliflower, Zucchini, Celery, Chili pepper and beterrave (Table 1-1). The expected production of vegetables in 2010C is estimated at 78,598 MT, which is equivalent to 12 tons of cereal equivalent.

Table 1-1: Vegetable seeds distribution in marchland, season 2010C

	Cabbage	Eggplant	Carrot	Tomato	Sweet pepper	Amaranthus	Red Onions	White onions	Frenchbeans	Lettuce	Cauliflower	Zucchini	Celery	Chili pepper	beterrave

Source: MINAGRI/Rhoda

The planned area of maize to be planted in 2010 C is estimated at 13,563 Ha. Maize to be planted is a new variety called SC514 which can produce between 5 and 9 tons per hectare (According to MINAGRI/CIP). Expected yield for this variety of maize is at least 5 tons per hectare, meaning that maize production in 2010 C will amount to 67,815 Tons.

In summary, crop production in 2010C is presented in the following table.

Crop	Area planned	Yield (Kg/Ha)	Production in Tons	Production in Kcal (10 ⁶)	Production (in cereal-equivalent) in Tons
Maize	13,563	5,000	67,815	218.7	67,815
Vegetable	2,601	30,218	78,598	41.1	12.7

Quantity in stock is estimated at 7,000 tons of maize, according to CIP.

The overall agricultural production of the season 2010B increased by **10%** in terms of cereal equivalent (or in terms of energy) in comparison with the same season in 2009B. Sorghum, beans groundnuts and banana production fell by 3%, 2%, 8% and 2% respectively. Some of the reason why the production of sorghum and beans decreased are outlined below:

- ^ Sowing during 2nd season has been delayed and so planted area reduced as season A corn was still in the fields.
- ^ Abundant rains at the time of flowering damaged beans in drought-prone zones of the Eastern and Southern Province.
- ^ Strong rains, flooding and landslides damaged crops in the Northwestern region.

Most importantly, maize, wheat, irish potato, sweet potato and cassava production recorded an increase of 62%, 32%, 26%, 10% and 9% respectively.

Banana production registered a fall of 2%, in comparison to 2009B. Area harvested for banana decreased by 3% as an impact of banana wilt %, which led to the decline of banana production.

The following graph shows that the share of tuber production is estimated at 51% like in 2009B. The share of cereal production stood at 21% in 2010B, from 6% in 2009B. This shift reflects the increase of maize and wheat production in the framework of CIP. The share of pulses and banana is 12% and 11% respectively.

The main cause of the production of cereals is the increase in area under cultivation, the use of chemical fertilizers and the improvement of the yield, especially for maize and wheat.

From 2009B to 2010 B, maize yield increased by 20%, from 1,551 kg/ha to 1,853 Kg/ha. Yield for sorghum increased by 2%, while yield for beans rose by 15%, due especially to climbing beans, while banana yield increased by 1%. In the category of tubers, sweet potato and cassava benefited from the prevailing rain during season 2010B. Detailed tables are presented in annex II.

Table 1-2: Harvested area, yield and production, 2009B and 2010B.

Crops	Harvested area by Crop (ha)			Yield (Kg/Ha)			Production (MT)		
	2009B	2010B	Change	2009B	2010B	Change	2009B	2010B	Change

4.3. Rainfall situation, season 2010B.

During the crop assessment, qualitative questions have been asked on the development of the season.

4.3.1. Perception of the farmers on rainfall, season 2010B.

In all Provinces, at least 75% of farmers declared that rains came on time, for only 11% saying that it was early. In general, 43% of the farmers said that rain has been too much. The distribution of farmers saying that rain has been too much is as follows: South (53%), West (51%), Kigali City (32%), North (31%) and East (27%). In Kigali City,

North and East, 63% to 66% said that rain has been enough. Less than one fifth (16%) of the farmers declared that rain caused much damage. In general, 60% of the farmers said that rain caused no damage (Table 1-3).

Table 1-3: Distribution of farmers (%) according to rain period, quantity and damages

	Kigali City	South	West	North	East	Rwanda
Rain period						
On time	79	87	85	80	75	82
Early	9	5	13	19	14	11
Late	12	9	2	1	11	7
Total	100	100	100	100	100	100
Quantity of rain

Damages						
Much damages	20	18	18	11	9	16
Little damages	47	20	27	20	25	24
No damage	33	62	54	69	66	60
Total	100	100	100	100	100	100

4.3.2. Decadal rainfall estimates by natural region.

The monthly bulletin produced by MINAGRI shows that at the start of the season (February), rainfall was above 100% of the long-term average. It went up since then and reached a peak of almost 300% in the third decadal of February and suddenly decreased and in the second decadal of March, it was less than 50% of the long-term average. During April, there was a consistent downward of rainfall. Though it increased during the first decadal of May and June, it was still below the long-term average. The long-term average is calculated for the period 1920 - 1980.

Graph 1-4: decadal rainfall trend by natural region, February - June 2010.

Source: MINAGRI monthly bulletin

4.3.3. Insects and diseases.

Nearly 90% of the farmers said that no insects affected crops. The distribution of farmers saying that no insects affected crops is as follows: Kigali City (100%), South (88%), West (89%), North (92%), East (98%). Also, 88% of the farmers declared that no diseases affected crop. The distribution, by provinces, of farmers reporting that no diseases affected crop is as follows: Kigali City (100%), South (87%), West (85%), North (87%) and East (95%)

Table 1-4: Distribution of famers (%) according to the presence of insects and diseases, by Province.

	Kigali City	South	West	North	East	Rwanda

Yes	0	13	15	13	5	12
No	100	87	85	87	95	88
Total	100	100	100	100	100	100

4.3.4. Use of fertilizers and improved seeds.

In general, 3% of the farmers used chemical fertilizers. No farmer used chemical fertilizer in Kigali City. In other provinces, the number of farmers that used chemical fertilizer is distributed as follows: South (2%), West (5%), North (7%) and East (1%). In Rwanda as a whole, 62% of the farmers declared that they used organic fertilizers.

The farmers saying that they used improved seeds represent 4% in Rwanda. The distribution of farmers declaring that they have used improved seeds is as follows: Kigali City (1%), South (6%), West (5%), North (4%) and East (2%).

Table 1-5: Distribution of farmers (%) according to the use of fertilizers and improved seeds, by Province.

	Kigali City	South	West	North	East	Rwanda

Total	100	100	100	100	100	100

4.3.5. Crop production in comparison to season 2009B.

Finally, it was asked to farmers to compare the production of 2010 season A with that of season 2009 A. The table below shows that 71% of the respondents reported that the production of 2010 A was normal to good, in comparison to season 2009 A. In Eastern Province, 57% of the farmers declared crop production was good, while in other provinces this proportion ranges from 24% to 31%.

Table 1-6: Crop production in comparison to 2009B, by Province.

	Kigali City	South	West	North	East	Rwanda
Comparison with 2009B						
Good	24	24	26	31	57	32
Normal	47	39	40	51	26	39
Bad	29	37	35	18	16	29
Total	100	100	100	100	100	100

4.4. Season 2010B development by selected crops.

Beans: in Rusizi, Nyamasheke, Kayonza and Nyagatare Districts, 55% to 64% of the respondents said that rain came on time for beans. In other Districts, at least 80% of farmers declared that rain came on time for this crop. Rain has been too much in Ngoma, Musanze, Gicumbi, Nyabihu, Ngororero, Karongi, Nyamagabe, Huye, Nyaruguru and Nyanza. In Gatsibo District, all the farmers said that rain was not enough, while in Nyamasheke and Rusizi, 33% to 46% of the farmers said that rain was not enough. In Nyaruguru and Huye, 73% to 79% of farmers said that rain caused much damages. This proportion is 54% in Nyamasheke, 69% in Gicumbi, 48% in Ngoma and 49% in Nyagatare.

Climbing beans: In the majority of the Districts, farmers said that rain came on time for climbing beans. It was too much in Nyanza, Gisagara, Huye, Nyamagabe, Muhanga, Karongi, Nyabihu, Rutsiro, Musanze, and Ngoma. It caused damage in most of the Southern Province, Rutsiro, Nyamasheke, Musanze and Gicumbi

Sorghum: In Southern and Eastern Provinces, rain came on time for this crop. In Rusizi District, farmers declared that rain came early. Rain was too much in South (except in Muhanga where it was not enough), in Kayonza and Nyagatare. It was not enough in Rusizi and Ngoma. Much damage has been declared in Nyaruguru, Muhanga, and Nyagatare.

Maize: In general, rain came on time for maize. It was too much in Nyanza, Huye, Nyamagabe, Nyabihu, Rutsiro, Musanze and Ngoma. It was not enough in Rusizi and to some extent, in Ruhango and Gakenke. It caused much damage in Gicumbi, Rusizi, Nyabihu and Muhanga.

Wheat: In general, rain came on time for this crop, except in Rusizi where it was early. It was too much in Nyaruguru, Huye, Ngororero, Nyabihu and Ngoma. In Nyaruguru, Karongi and Nyabihu District, 44% and 25% of the farmers said that it has caused too much damage for this crop.

Cassava: For almost all the Districts, rain came on time for this crop, except in Nyabihu and Nyagatare where 65% and 33% respectively said that it came early. For this particular crop, rain too much in Nyanza, Gisagara, Huye, Nyamagabe, Muhanga, Ngororero, Nyabihu, Rutsiro, Nyamasheke and Musanze. In the area where it caused much damage, the proportion of farmers is distributed as follows: Nyanza (16%), Nyaruguru (26%), Nyabihu (32%) and Musanze (40%).

Sweet potato: in general, rain came on time, except in Nyagatare. It was too much in Nyanza, Huye, Karongi, Nyabihu, Rutsiro, Nyamasheke, Rulindo, Musanze and Nyagatare. Elsewhere, it was enough. The proportion of farmers declaring that rain

caused too much damage in some districts is distributed as follows: Nyagatare (40%), Gicumbi (23%) and Nyaruguru (23%). In other districts, it caused little damage.

Irish potato: in almost all the districts, with the exception of Nyagatare and Rutsiro, rain came on time for this crop. It was too much in Nyanza, Gisagara, Muhanga, a great part of Western and Northern Provinces, in Kirehe, Ngoma and Nyagatare. In Karongi, Gakenke and Ngoma, the proportion of farmers saying that rain was not enough is 20% and 33% respectively. The rains caused much damage in Northern Province and to some extent, in the Western Province.

4.5. Food Security

The production of the 2010B season led to the improvement of national food security. Carolific needs are calculated for the production of the season only. In all provinces, carolific needs are covered at a rate greater than 100%. In the Southern Province, the lowest carolific coverage is encountered in Nyaruguru District, with a maximum of 183% in Ruhango District. In the Western Province, carolific coverage ranges at 108% (Rutsiro) and 165% (Nyabihu). In the North, the minimum carolific coverage is estimated at 104% (Rulindo) and the maximum at 150% (Gicumbi). In Eastern Province, carolific needs are covered at a minimum rate of 126% (Rwamagana and Bugesera) and 233%(Kirehe) (Table 1-7).

Table 1-7: Estimated energy availability in percent of the requirement (2100 kcal/person/day) from local food production in Rwanda by Province, Season 2010B

Province	Min	Max
South	103	183
West	108	165
North	104	150
East	126	233

The total and per capita production of energy is shown in figures 1-5 and 1-6. In terms of kcal production (both from crop and anima), only five districts, namely Kamonyi and Ruhango (South), Nyabihu (West) Gicumbi (North) and Kirehe (East) produced more Kcal than other districts (figure 1-5). In terms of energy coverage per personne per day, these districts, except Gicumbi, have also the highest coverage, while Nyanza moves from light green (graph 1-5) to dark green (graph 1-6). The fact is that the population of the districts is taken in consideration in the second map.

Graph 1-5: Total Crop and animal production in energy (Kcal) by district, season 2010B.

Graph 1-6: Energy coverage per person day in percent of recommended 2,100 Kcal/per/day, season 2010B.

Total roduction in Kcal increased by 12%, in comparison with 2009B. Protein and lipid production increased by 15.2% and 12.5% respectively. Kcal from animal production

decreased by 0.4% while protein and lipid production from livestock increased by 3.8% and 0.7% respectively.

Table 1-8: Production in Kcal, proteins and lipids

	2008B	2009B	2010B	%age change	
				2009B/08B	2010B/09B
Kcal (1 000 000 000)	3,897.10	4,338.3	4,993	11%	12.8%
Proteins (1 000 T.)	81	92.2	105	14%	15.2%

N.B. : Adult humans require 2100 kcal/capital/day, 59 g of protéins and 40 g of lipids (source ENA/MINAGRI)

The national food balance sheet shows a surplus of 158,000 MT of cereal equivalent. The balance sheet includes estimated production of maize and vegetables for season 2010 C. When season C is excluded, the balance sheet shows a surplus of 89,000 MT of cereal equivalent. Data on Imports and food aid are not available and hence not included in this balance (Table 1-9).

Table 1-9: Rwanda Food Balance for 6 months from July to December 2010

	(*1000 MT)
I. AVAILABILITY =1+ 2+3+4+5	1403
1. Stock	7
2. Crop production 2010B	1,467

Annex III: Methodology.

1.1. Sampling methodology

1.1.1. Target population

The target population for the crop assessment survey is composed of all rural and urban households where there exist strong agricultural activities.

1.1.2. Stratification

A stratified two-stage sample design has been used for the ENA. The sampling frame was stratified by Province (City of Kigali), urban and rural. The urban strata consisted of Kigali-City and other urban, while the rural part of each province was treated as a separate stratum. Data are representative at District level.

1.1.3. Sample selection procedure.

Within each stratum, the sample enumeration areas were selected systematically with probability proportional to size (PPS), where the measure of size for each enumeration area was based on the number of households from the sampling frame. Within each enumeration area, 12 households have been selected with simple random sampling, meaning that all households had the same probability to be selected.

1.1.4. Estimation procedure

In order for the sample estimates from a particular survey to be representative of the population, it is necessary to multiply the data by a sampling weight, or expansion factor. The basic weight for each sample household would be equal to the inverse of its probability of selection (calculated by multiplying the probabilities at each sampling stage).

1.2. Estimation of area under cultivation.

1.2.1. Area measurement

The shape of cultivated areas is not always of the regular form (triangle, rectangle...), but most of the fields under cultivation have rectangular shape (square or rectangle), others are triangular (triangle). We encounter also fields that have irregular shape, having 5 sides or above. In one or other case, the area measurement has been simplified as follows:

- a) **Field of rectangular shape**: area is obtained by multiplying the length and the width.
- b) **Triangular fields**. The enumerator measures the length of the base side and that of the height, and the area is equal to the base multiply by the height divide by 2.

- c) **Fields of irregular shape.** In this case, a field of such shape has been divided into several plots of regular shape, in order to facilitate the calculation of the area of the entire field, as shown in the following figure.

Example : A field of irregular shape with 7 sides.

The perimeter of the above field is shown by the thin black lines. The field is not a rectangle, nor a triangle, neither of a known geometric form. In this case, area measurement has been done using procedure described in b, since the field is composed of triangles. The total area of the field is the sum of the areas of the triangles that constitute the field. One or more plots were randomly selected for the purpose of estimating the yield.
